**Status: Proposal**

**Title: Support of SVG1.2 for LASER**

**Authors: Jean-Claude Dufourd, Olivier Avaro and Cyril Concolato**

## **Introduction**

It is important to leverage industry's growing acceptance of SVG to improve LASER chances of success. In particular, in the mobile arena, 3GPP mandates the use of SVG Tiny in its releases 5 and 6 within the framework of MMS. Thus, SVG is seen by many actors as a must, and supporting a subset of SVG in LASER would be a great asset.

Yet SVG has the same problems as BIFS in terms of size and performance. Even though one SVG profile is called Tiny, its implementations are well above the target range of LASER:

- BitFlash website: SVG Tiny player on mobiles usually around 500K (870K with scripting).
- CSIRO player for PocketPC (from W3C website): 390K
- eSVG player for PocketPC: around 500K (plus maybe DLLs)

With hindsight, BIFS was not so bad with IBM's Java player around 400K (including video and audio decoding).

There is at [www.tinyline.com](http://www.tinyline.com), a Java implementation of a small subset of SVG, called Tinyline (version 1.6). The author calls the implemented subset SVG Minute. 30 of the 32 elements of SVG Tiny are implemented, and definitely not all attribute combinations. The result is still of amazingly good quality, with a code size of 168K (class files = memory usage in the handheld), and 95.1K (zipped in a JAR file = size of installer message when sent over the air). Our evaluation of the code is that its quality is very high, and we believe it is an excellent reference point.

To achieve the LASER target of 50-100K, there is a definite need for drastic profiling of SVG Tiny. By comparison and to prove this target is feasible, our proto-LASER Java player has a code size of 79.5K(classes) and 42.7K(zipped).

# SVG Complexity and Profiling

## *Estimation of the Problem Scale*

As there was “node bloat” in BIFS, there seems to be “feature bloat” in SVG, already in the so-called “Tiny” profile. In this document, we propose a way of measuring the complexity of the standard. In SVG Tiny, there are 32 XML elements (nodes in BIFS), with an average **20** XML attributes (fields in BIFS) per element. The total size is close to 700 allowed element-attribute pairs in total. The list is given in an annex to this document. No wonder the code size in the 500K range.

By comparison, our proto-LASER solution has 30 element-attribute pairs for SAF and 180 for LASER, including 30 for BIFS-like updates and 150 for scene.

So the target is a **feature reduction of 4 to 8**.

## *Binary vs. XML Text*

Our proto-LASER implementation includes a binary parser à la BIFS: clearly, binary parsing is smaller and faster than XML parsing. Here is an estimation of the difference in size.

In Tinyline, the parser size is approximately 66K (classes) and 30K (zipped). This accounts for an incomplete SVG Tiny (XML) parser, without DOM or scripting.

In our proto-LASER implementation, the parser size is 34.1K (classes) and 14.6K (zipped).

Clearly, with a factor of 2 in code size, and a significant speed up (not measured), a binary format is much better for small embedded devices.

## *SVG Tiny Features*

SVG is loaded with authoring facilities and features useful in text but painful in binary. These features are definitely assets in the PC/Internet world, where easy textual authoring is a key to the acceptance of a format. The mobile world does not have these requirements, and can even be said to have conflicting requirements. Here is a list of problematic features:

- switch: the SVG switch is a construct that enables a **varying “level of requirements” within one scene**. While this is a very handy capability for device independence, it is much too complex for embedded devices.
- **property inheritance**: the ability to place e.g. a color on the primitives or on any of the elements above it is again useful in terms of authoring, but multiplies the number of possibilities, hence the complexity of the code to implement the “color with inheritance” feature.
- multiple primitives when path/shape can do it all: having “rect” and “path” is not useful on embedded devices, because what “rect” does, “path” can do very easily. Thus, only “path” is needed as a graphics primitive.
- foreignObject: SVG has an element for including “something else” in the scene tree. This is as close as ApplicationWindow node of BIFS as we can think. This could intended to be used for e.g. video. Clearly, MPEG (and SMIL) has another way of doing it, by defining Audio and Video elements.
- complete text rendering system: the complexity of the text rendering systems is big. We have recently acknowledged within MPEG the need for better text, but the SVG text level is still overkill for the smallest devices.

- multiple ways of doing something: SVG does not have the “one-tool-one-functionality” principle that MPEG has, and this can be felt throughout the spec.
- in SVG 1.2: the SVG WG has decided to put simple gradients and text flow layout in SVG Tiny, something that brings SVG Tiny even further than the target code size.
- path specification with all those options: the multiple types of curves that path can do are overkill on small devices.
- multiple transform specifications: the ability to specify transformations in multiple ways has a high cost in lines of codes
- color keywords: the ability to specify colors by keyword is very expensive in terms of 1) code size: the table needed to convert the names to RGB and 2) compression: the encoding of strings is worse than the encoding of RGB.
- defs: this grouping of the DEFed elements is “nice” but does not help code size or implementability in any way, because it is optional. Moreover, it can be done with existing nodes. Therefore, we want to remove it.

## Required Extensions

To accommodate some of MPEG assets in graphics, here are proposed extensions of SVG:

- Audio and Video elements
- updates à la BIFS: Insert/Replace/Delete, value/node/indexed... to replace the “discarded” XML Events.
- cursor, textual input and keyboard management:
  - o cursor: for terminals without pen or mouse (the majority), the ability to designate an actual shape in the content to be a virtual cursor is very effective. This virtual cursor/shape is to be moved by key presses (e.g. with the joystick which emulates key presses), and when the “FIRE” button is pressed, the current position of the virtual cursor is used instead of a mouse position.
  - o textual input: this is an interface to the typing assistance software available in most terminals.
  - o keyboard management: basically, this is the BIFS KeySensor (specialisation of the InputSensor).
- declarative scripting : as programmatic scripting is too expensive for the target code sizes, we suggest to use BIFS-like scripting, based on concepts close to Conditional, Valuator ...
- the ability to save and restore small chunks of data in an application-linked manner has been found key to many mobile services. This should be done in the manner of the RMS feature of MIDP1.0.

## Proposed Profile

To be discussed with SVG experts, here is a first shot at pruning SVG Tiny. For easier reading, we have used color coding in the annex describing all of the SVG Tiny 1.1 features:

- red/italics means not included
- blue/plain means under consideration for a higher profile of LASER

- black/bold means proposed for inclusion in LASER.

## **Acknowledgements**

Some of the work leading to this contribution was funded by the European Commission as part of the DANAE Project.

## Annex: all of SVG Tiny allowed element-field pairs
